Introduction

Customer Churn Prediction & Retention Framework is a data-driven system designed to identify customers who are likely to stop using a company's products or services. Customer churn is one of the major challenges faced by businesses because losing customers can reduce revenue and increase the cost of acquiring new customers. By analyzing customer data such as usage patterns, subscription details, transaction history, and customer behavior, machine learning techniques can predict the probability of customer churn.

This project aims to develop a predictive framework that helps organizations detect potential customer loss at an early stage and implement effective retention strategies. The framework uses data analytics and machine learning algorithms to classify customers as likely to churn or remain loyal. The insights generated by the system enable businesses to improve customer satisfaction, enhance customer relationships, and increase profitability.

Problem Statement

Many organizations experience customer loss due to competition, dissatisfaction, poor service quality, or changing customer needs. Identifying customers who are likely to leave a service is difficult when dealing with large amounts of customer data. As a result, companies often fail to take timely actions to retain valuable customers.

The problem addressed in this project is to build a Customer Churn Prediction & Retention Framework that can analyze customer information, predict the likelihood of churn, and provide recommendations for customer retention. The proposed system helps businesses reduce customer attrition, improve customer loyalty, and make informed decisions using predictive analytics and machine learning techniques.
